

Hysterectomy

Definition

Hysterectomy is the surgical removal of the uterus (womb) resulting in inability to become pregnant (sterility) and immediate cessation of menstruation. It is a common operation and may involve removal of the cervix, ovaries and fallopian tubes at the same time.

Please discuss all aspects of this surgical procedure, its risks and benefits and any possible alternative therapies. Your health care provider will help you decide which type of hysterectomy is appropriate for you, depending on your indications for surgery and your medical history.

Types of hysterectomy

1. Total or simple hysterectomy - removal of the entire uterus, including the cervix.
2. Subtotal (partial; supracervical) hysterectomy - removal of the uterus above the cervix, leaving the cervix intact. In this case, regular Pap smear is advised after the surgery
3. Radical hysterectomy - removal of the uterus and surrounding tissues.
4. Total hysterectomy with bilateral salpingo-oophorectomy - removal of the uterus, cervix, both fallopian tubes, and both ovaries. When both ovaries are removed, you will experience what is called surgical menopause. A unilateral oophorectomy procedure leaves one ovary behind.

Reasons for the procedure

- Endometriosis.
- Uterine fibroids.
- Heavy menstrual bleeding (after failed medical therapy and not suitable for other minimally invasive alternatives)
- Uterine prolapse.
- Endometrial hyperplasia.
- Severe, chronic (long-term) infections, such as pelvic inflammatory disease.
- Chronic pelvic pain.
- Ovarian growths, if persistent or symptomatic.
- Pelvic adhesions.
- Cancer of the uterus, cervix, ovaries, or fallopian tubes.

Description of the procedure

- A general anaesthetic will be administered. The procedures may take 1 to 2 hours.
- Antibiotics to prevent post surgical infection is usually given at the start of surgery.
- A urinary catheter is placed into the bladder.
- With an ABDOMINAL HYSTERECTOMY, an incision is made in the abdomen (horizontal or vertical, depending on the diagnosis and/or size of the uterus). The abdominal organs are examined. The uterus is cut free and removed. Other organs and tissue may be removed. The vagina is often closed with sutures at its deeper end. The surgical wound (including the skin) is closed in layers with sutures.
- With VAGINAL HYSTERECTOMY, the procedure is done vaginally. An incision is made in the upper end of the vagina. The cervix is separated from the bladder in front. The ligaments containing the blood vessel to the uterus are clamped with a surgical clamp, cut and tied with sutures. The uterus and other structures are brought out through the vagina, and the cut end of the vagina is sutured. This technique is often used in cases of uterine prolapse or when vaginal repairs are necessary for related conditions. When a vaginal hysterectomy is performed, any sagging of the vaginal walls, urethra, bladder, or rectum can be surgically corrected at the same time. This is also known collectively as pelvic floor repair. For example, colporrhaphy is a vaginal procedure to reestablish the supports between the bladder and vagina to fix a cystocele (descend of the bladder).
- LAPAROSCOPIC ASSISTED VAGINAL HYSTERECTOMY (LAVH) is a combined procedure that can aid in the removal of the uterus vaginally when it otherwise would require an abdominal incision. This

procedure is performed with the aid of a laparoscope (a tiny telescope that is hook up to a monitor), which is inserted through the navel. Instruments are inserted through additional tiny incisions in the abdomen and are used to cut and separate the uterus from the surrounding attachments. Once this is completed, the uterus is then removed through the vagina.

- Both ovaries and the fallopian tubes may be removed at the same time in certain women (especially those with suspected or proven cancer cases, those nearing menopause or already menopause).

Possible complications

In general, the risk of complications is low in those fit and healthy women undergoing surgery for benign conditions. The risk is increased if there is associated medical illness (poor fitness for surgery), elderly women, women undergoing repeated abdominal surgery or presence of cancer. The complications are :

- Excessive bleeding (may require a blood transfusion).
- Surgical wound infection.
- Inadvertent injury to the bowel, bladder or ureters (the tubes going from the kidneys to the bladder), or nerve damage.
- Anaesthetic complications.
- Urinary tract infection.
- Respiratory infection, particularly pneumonia.
- Urinary retention requiring continued use of a catheter.
- Bowel obstruction.
- Pelvic pain.
- Blood clots in calf veins, which can travel to the lung, causing lung damage.
- Fistula (abnormal opening) between the vagina and bladder or rectum.

Before the operation

- Consent for operation should be signed.
- Relevant investigation that may be taken will depends on your medical illness and age. This may include blood tests, ECG (electrocardiogram) and chest X-ray.
- A small enema is given the night before or on the morning of the surgery to empty the bowel. Shaving of the operative site is done before surgery.
- You are required to fast for at least 6 hours before surgery (no food or drinks at all for 6 hours). For example, if the surgery is in the morning, you should skip breakfast. If it is in the afternoon, you can have an early light breakfast (eg. tea/coffee/milo and toast) but make sure that this is taken at least 6 hours before the surgery. Please reconfirm this with your doctor.

Post operative care

- Hospital stay may be 3 to 5 days.
- Food or drinks are not allowed immediately following the surgery. Fluids will be given via an intravenous line. Your doctor will review periodically to decide when to start orally. Initially, only clear liquid diet is allowed until the gastrointestinal tract functions again. Then eat a well-balanced diet to promote healing.
- Depending on the diagnosis and the extent of surgery, a small drain (tubing) may be inserted into the abdominal cavity after the surgery to allow any excess blood to drain out. This is usually removed in 24 to 48 hours later.
- There will be a urinary catheter in the bladder to allow drainage of urine and is usually removed the following day.
- Pain relief medication will be given via injection and later change to oral tablet.
- Antibiotics is given at time of operation and may be continued if there is a risk of infection.
- It is important to mobilize as soon as possible, since it helps prevent complications, such as blood clots and pneumonia,
- Gas pain (abdominal wind) can be a problem following the operation for some women. Early mobilization

will help to reduce the wind. If the problem still persists, medication can be prescribed for relief.

- Wound dressing will be removed before discharge and the operation area sprayed with an Opsite dressing. The wound will be kept exposed.
- For Abdominal Hysterectomy, non absorbable sutures are usually removed from the skin incision on the seventh day. If absorbable suture is used, then the suture need not be removed. It will dissolve by itself after a few weeks.
- For Laparoscopic or Vaginal Hysterectomy, absorbable suture is often used. Therefore, the stitches need not be removed.
- Once home, someone should be available to help care for you for the first few days.
- Avoid douching, swimming, and baths for 4 weeks.
- Shower as usual. Wipe dry the incision site with a clean dry towel after the shower.
- Vaginal bleeding will last for few days to one week. Use sanitary napkins—not tampons—to absorb blood or drainage.
- After effects of surgery may include constipation, urinary symptoms and fatigue.
- Following removal of the uterus, you will no longer have your monthly periods or be able to become pregnant.
- It's still necessary to have regular pelvic examinations after hysterectomy, especially if the ovaries or the cervix are conserved. ; if you still have your cervix, you'll still need to have a Pap smear.

Activity

- To help recovery and aid your well-being, resume daily activities, including work, as soon as you are able. Heavy lifting and strenuous activity should be avoided. Recovery at home may take 2 to 3 weeks, with full activities resumed in 6 to 8 weeks.. Incisional numbness, occasional aches and pains may last for another few weeks. For laparoscopic hysterectomy and vaginal hysterectomy recovery time is much quicker than abdominal hysterectomy.
- You can resume driving after 4 weeks, provided full mobility has returns and pain-killers medications are no longer required. Please ask your doctor if you are not sure.
- Sexual relations may be resumed in 6 weeks (or when advised). Most women experience no change in sexual function; some report improvement, while others have a worsening sexual function, specifically loss of libido (sexual desire). Intercourse may be uncomfortable for a period of time. You may feel bruised or sore, the vagina may have shrunk and vaginal dryness can occur. Time, patience, trying different techniques and good communication with your partner should help alleviate any problems and increase your pleasure during intercourse.

See your doctor if there is:

- Increasing pain, swelling, redness, discharge or bleeding in the surgical area.
- Vaginal bleeding which soaks more than 1 pad or tampon each hour.
- The urge to urinate frequently, especially if associated with pain and abnormal urine colour.
- Persistent and abnormal vaginal discharge.
- Increasing nausea and vomiting, with or without abdominal distention.
- Short of breath or feel faint.
- Signs of infection, including headache, muscle aches, dizziness or a general ill feeling and fever.
